**Abstract.** The occurrence of *Mischocyttarus consimilis* Zikán, *Mischocyttarus ignotus* Zikán, *Mischocyttarus nomurae* Richards and *Mischocyttarus paraguayensis* Zikán for the state of Minas Gerais and *Mischocyttarus garbei* Zikán for the state of Rio de Janeiro are registered for the first time, collected through active search and attractive traps.

**Keywords:** Distribution; Polistinae; Survey; Taxonomy.

## Novos Registros de Vespas Sociais (Hymenoptera: Vespidae) em Floresta Estacional Semidecidual Montana e Mata Seca em Minas Gerais e na Mata Atlântica no Estado do Rio de Janeiro

**Resumo.** Neste trabalho é registrado pela primeira vez a ocorrência de *Mischocyttarus consimilis* Zikán, *Mischocyttarus ignotus* Zikán, *Mischocyttarus nomurae* Richards e *Mischocyttarus paraguayensis* Zikán para o estado de Minas Gerais e *Mischocyttarus garbei* Zikán para o estado do Rio de Janeiro coletadas por meio de busca ativa e armadilhas atrativas.

**Palavras-Chave:** Distribuição; Levantamento; Polistinae; Taxonomia.

Biodiversity should not be evaluated in terms of number of species, but also on the perspective of interactions and species distribution, to enhance the preservation of natural ecosystems (DEL-CLARO 2004). In this regard, the biological characteristics, distribution, abundance and richness of social wasp interactions make them a key group in ecosystems with important ecological roles as predators (RICHTER 2000; ELISEI *et al.* 2005; PREZOTO *et al.* 2005; PREZOTO *et al.* 2006; SANTOS *et al.* 2007a; SANTOS *et al.* 2009), bioindicators (SOUZA *et al.* 2010a) and pollinators (HEITHAUS 1979; HERMES & KOHLER 2006; SANTOS *et al.* 2009).

In Brazil, despite the great diversity of social wasps, little is known about their ecology and distribution along the Brazilian biomes (RICHARDS 1978; CARPENTER & MARQUES 2001; SOUZA & ZANUNCIO 2012).

In the last decade, social wasp diversity studies have been conducted in a semideciduous forest in the state of Minas Gerais (SOUZA & PREZOTO 2006; ELPINO-COMPOS 2007), although not including the regions South and Zona da Mata. There are also no records of studies on these insects for the tropical dry forest in Minas Gerais, and the coastal region of Rio de Janeiro state. The goal of this study was to provide information about the occurrences of social wasps in two Brazilian ecosystems, the Atlantic Forest and tropical dry forest, in the states of Minas Gerais and Rio de Janeiro.

The study was conducted in the municipality of São Gonçalo do

Sapucaí (21°53'20" S, 45°35'24" W), southern Minas Gerais, in areas of semideciduous seasonal montane forest in the period from March 2012 to February 2013; in the Parque Estadual do Brigadeiro (20°42'55" S, 42°26'51" W), forest zone of Minas Gerais, in the period from January to December 2011, in semideciduous seasonal montane forest formations, in the municipality of Montes Claros (16°44'13" S, 43°51'53" W), northern Minas Gerais state, tropical dry forest area, November-December 2011, and in the Atlantic Forest in the district of Trindade (20°31'29" S 29°19'29" W), municipality of Paraty, State of Rio de Janeiro in October 2009 (Figure 1).

The collection of social wasp species was conducted using the methodology of active search (entomological net) and attractive traps (using passion fruit, guava, mango and sardines) (SILVEIRA 2002; SOUZA & PREZOTO 2006).

The social wasp species were identified with the aid of identification keys and comparison with specimens from the entomological collection of the Entomology Department of Universidade Federal de Lavras (UFLA) and/or by Prof. Dr. Orlando Tobias da Silveira of the Emílio Goeldi Museum, Belém, Pará. Specimens were deposited in the Emílio Goeldi Museum and the entomological collection of the Federal Universities of Viçosa and Lavras.

New records for the state of Minas Gerais are *Mischocyttarus consimilis* Zikán; *Mischocyttarus ignotus* Zikán; *Mischocyttarus nomurae* Richards and *Mischocyttarus paraguayensis* Zikán (Hymenoptera: Vespidae), the first species being unprecedented in Brazil (RICHARDS 1978), increasing from 96 to 100 species of social wasps for the state (SOUZA & ZANUNCIO 2012). One new record for the state of Rio de Janeiro is *Mischocyttarus garbei* Zikán (Hymenoptera: Vespidae) (Figure 1).

We recorded seven colonies of *M. consimilis* (Figure 2) in the municipality of São Gonçalo do Sapucaí. Nesting occurred on different substrates, such as banks, leaves and roots. This species had previously been recorded only in the state of Mato Grosso do Sul (RICHARDS 1978; TORRES et al. 2011). There was a record of an *M. ignotus* nest (Figure 3) also in São Gonçalo do Sapucaí, nesting inside the forest. This species was previously recorded for the states of São Paulo and Rio Grande do Sul (RICHARDS 1978).

Although the genus *Mischocyttarus* forms the largest group of social wasps, with nine subgenera and 245 species, the registration of new collecting records of this genus is due to a sum of factors such as small nests and few individuals, which together with little studied regions like Atlantic Forest areas, increases the chance of unprecedented registrations (COOPER 1998; SILVEIRA 2008).

The registration of the *M. nomurae* occurred in December 2011, which corresponded to the rainy season, when five specimens were captured using an attractive trap with passion fruit in the city of Montes Claros, Minas Gerais, there being no record of the colonies. Several studies show the effectiveness of this bait (SOUZA & PREZOTO 2006; NOLL & GOMES 2009; SOUZA et al. 2010b; SOUZA et al. 2012) as an attractive source to capture social wasps, through the olfactory signals due to the strong fragrance emitted by the fruit (COLLET et al. 2003; NAUG & WENZEL 2006; WARRANT et al. 2006; McPHERON & MILLS 2007; SANTOS et al. 2007b).

*Mischocyttarus paraguayensis* was recorded in São Gonçalo do Sapucaí, with the only registered colony built on a plant substrate. In Parque Estadual do Brigadeiro this species was also sampled, and only one colony recorded (Figure 4). The species also occurs in the states of Rio Grande do Sul and Santa Catarina (RICHARDS 1978).

A colony of *M. garbei* (Figure 5) was recorded in a Bromeliaceae in the rainy season in the district of Trindade, municipality of Paraty, Rio de Janeiro. Bromeliads have very rigid leaves and are possibly shelter for their nests against the action of rain, a situation already recorded in other plant species in Minas Gerais, such as the species *Mischocyttarus confusus* (Zikán) in Mrytaceae in Cerrado areas, *Protopolybia sedula* (Saussure) in Bromeliaceae in a rupestrian field (SOUZA & PREZOTO 2006; SOUZA et al. 2010b), and *Protopolybia* sp. and *Polybia platycephala* (Richards) on ornamental plants in public gardens (PREZOTO et al. 2009). This species has only been registered in the state of Espírito Santo (RICHARDS 1978).

These new distribution records of social wasps in the states of Minas Gerais and Rio de Janeiro suggest that many species are still unknown to these states. Despite efforts to know the diversity of social wasps in Minas Gerais in the last decade, the number of species should be higher, considering the territorial state size, and the fact that some ecosystems are not sampled in an expressive way. For the state of Rio de Janeiro, there are few areas studied, considering the existence of large Atlantic Forest fragments, suggesting that the number of species should also be larger than currently known.

In this sense, it is worth emphasizing the importance of further studies in these states in order to obtain specific information from these larger bodies, which will surely increase the knowledge of the social wasp fauna.
